

# Sampling Principles (part 2)

Ryan Miller

# Sampling and Statistical Inference

- ▶ A *fundamental goal* of statisticians is to use information from a sample to make *reliable* statements about a population
  - ▶ This idea is called **statistical inference**

# Statistical Inference - Notation

Statisticians use different notation to distinguish *population parameters* (things we want to know) from *estimates* (things derived from a sample). For a few common measures, this notation is summarized below:

	Population Parameter	Estimate (from sample)
Mean	$\mu$	$\bar{x}$
Standard Deviation	$\sigma$	$s$
Proportion	$p$	$\hat{p}$
Correlation	$\rho$	$r$
Regression	$\beta_0, \beta_1$	$b_0, b_1$

For example,  $\mu$  is the mean of the target population, while  $\bar{x}$  is the mean of the cases that ended up in the sample.

- ▶ Ideally we are working with a simple random sample, so the *uncertainty* introduced by the random sampling scheme is the *only reason* for sample estimates differing from their population parameters
- ▶ Put differently, very few samples should be expected to produce estimates that *exactly* equal the population parameter
  - ▶ The randomness involved in which cases were selected leads to variability in estimates from different samples

# Sampling Variability

# Bias and Variability

Putting things together, we've now discussed *two reasons* why an estimate might not accurately reflect a population parameter, **bias** and **variability**:

# The Role of Sample Size

- ▶ The effects of sampling variability are reduced by selecting larger samples
- ▶ The effects of sampling bias will remain or might even be exacerbated by selecting larger samples

# Digression - The Vietnam Draft

- ▶ During the Vietnam War, the US government conducted a draft lottery of all eligible adult men serve in the armed forces
  - ▶ The lottery was based on birthdays and televised on Dec 1, 1969
  - ▶ 366 capsules placed into a bin for a host to draw one-at-time, the results are shown below:

date	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
1	305	86	108	32	330	249	93	111	225	359	19	129
2	159	144	29	271	298	228	350	45	161	125	34	328

# Digression - The Vietnam Draft

- ▶ A potentially better display of the draft results is the scatterplot below
  - ▶ Does the sampling procedure used in the lottery appear to be fair?

# Digression - The Vietnam Draft

Statisticians weren't so sure. . .

# Digression - The Vietnam Draft

- ▶ The observed correlation coefficient between day and draft number was -0.226
  - ▶ The histogram below shows the correlation coefficients from 10,000 simulated random lotteries
  - ▶ Do you think the draft was fair?

## Digression - The Vietnam Draft

- ▶ If the lottery were fair, it would be *extremely unlikely* to see this relationship between later birthdays to have lower drafter numbers
  - ▶ The  $p$ -value is less than  $1/10000$

## Digression - The Vietnam Draft

- ▶ If the lottery were fair, it would be *extremely unlikely* to see this relationship between later birthdays to have lower draft numbers
  - ▶ The  $p$ -value is less than  $1/10000$
- ▶ Many believe this is an artifact of bias in the sampling procedure
  - ▶ The capsules were added to the bin sequentially and likely weren't mixed properly
  - ▶ This put the earlier dates closer to the bottom and made them less likely to be drawn early on

# Conclusion

- ▶ The process by which data are collected is almost always *more important* than what the statistician does to analyze it when it comes to making reliable conclusions
  - ▶ It is very difficult for a data analyst to retro-actively address sampling bias in a suitable manner, and any methods for doing so well beyond the scope of this course
- ▶ The lesson is to always carefully consider the representativeness of your data before generalizing from them
